12   to copyright protection. The copyright owner has no objection to the facsimile reproduction by

13   anyone of the patent document or the patent disclosure, as it appears in the Patent and

14   Trademark Office patent file or records, but otherwise reserves all copyright rights whatsoever.

BACKGROUND OF THE INVENTION

1   **1.**   **Field of the Invention**

The present invention relates in general to computer file systems, and more particularly to an extensible file access method for accessing a foreign file system from a data processing system with a native file system, said foreign file system and said native file system implementing different file system protocols.

2. Description of the Related Art

A file system comprises the logical structures and software function routines used to store, organize, and access information stored on a computer system's logical or physical storage media, such as a diskette, hard disk system, or optical storage. A variety of file systems have been developed to address various needs. For example, personal computer file systems comprise: File Allocation Table (FAT); Virtual FAT (VFAT); 32-Bit FAT (FAT32); New Technology File System (NTFS); and High Performance File System (HPFS). File systems for mid-range computers comprise: Unix File System (UFS), Network File System (NFS), and AS/400. Mainframe computer file system offerings comprise: Virtual Storage Access Method (VSAM); Sequential Access Method (SAM); Partitioned Data Set (PDS); and Object Access Method (OAM). File systems are not limited to these lists which are merely illustrative subsets of the numerous variety of file systems.

The various computer architectures and computer operating systems may use different file systems, thus organizing and accessing the information in different ways. Generally, these different file systems are incompatible, meaning that files created by one file system may not be accessed by another file system.. A user may have a computer system supporting a particular file system, a native file system, and the user may wish to access and use information stored in a file system other than the native file system, a foreign file system. The user may need to access the foreign file system information for any of a number of motivations, such as to migrate the information to a replacement system, to archive the information, or to share the information among different systems.

Conventional systems have addressed this user need to access foreign file systems in a number of ways. The earliest conventional approach was to create a duplicate of the information and to convert the information in this duplicate from the native file system format to the foreign file system format. This approach is exemplified by patents such as U. S. Patent

1	Number 5,537,592, "System and Method for Reading and Writing Disks Formatted for an

2	Operating System Foreign to the Host Computer;" U. S. Patent Number 5,742,818, "Method

3	and System of Converting Data from a Source File System to a Target File System;" Japan

4	Patent Number 9231114A, "File System Conversion System;" and "Japan Patent Number

5	6243020A, "File Conversion Device." U. S. Patent Number 5,537,592 is representative of this

6	approach, and in particular teaches a set of processes and data structures that allow transfer of

7	user specified files between differently formatted disks. The processes identify the file format

8	of the source and destination disks, retrieve the source files in the source file format, store the

9	source files in a common format in memory that allows the directory hierarchy of the source

10	disk and destination disk to be maintained, translate the contents of text source file records to

11	the record format of the destination file system if desired, create directories and headers if

12	necessary for the foreign disk for the transferred files, and store the files on the destination disk

13	in a host file format. The user can then access and modify the files in the host file format using

14	a host computer system. This approach is only a partial solution in that it only converts and

15	reformats the information, it does not convert the software functions. The native file system

16	can still only access information stored in the native file system format; it cannot access

17	information stored in the foreign file system format, nor can it use the foreign file system

18	software functions.

19

20	Another conventional solution is to install and support both file systems on the same

21	computer system., effectively making the foreign file system an additional native file system.

22	This solution is taught by U.S. Patent Number 5,363,487, "Method and System for Dynamic

23	Volume Tracking in an Installable File System," which permits a single operating system to

24	access a storage medium formatted in accordance with differing file systems. Generally, the

25	operating system identifies which of a plurality of file system drivers is appropriate for reading

26	a particular storage volume and, thereafter, associates the identified file system driver with the

27	particular storage volume. Similarly, U. S. Patent Number 5,911,776, "Automatic Format

28	Conversion System and Publishing Methodology for Multi-user Network," provides a set of

29	multiple shadow file converters connected to a source file of an original document. Each

1 shadow file converter enables the transformation of the original source file format into a

2 particular other specific type of file format. However, providing all the permutations of the

3 different types of file systems ported to the different types of operating systems and computer

4 hardware architectures is probably not commercially feasible.

5

6 A more robust conventional approach is to directly convert file system requests from

7 one file system protocol to another. For example, a client system, having a native file system

8 protocol, may issue a request in the client's native file system protocol to a server. However,

9 the server uses a foreign file system protocol which is different form the client's native file

10 system protocol. A file system protocol converter translates the client's request from the

11 client's native file system protocol to the server's foreign file system protocol. The file system

12 converter may also convert the server response by reformatting the response's information from

13 the server's foreign file system format to the client's native file system format. This type of

14 direct file system protocol conversion is taught by: U. S. Patent Number 5,218,697, "Method

15 and System for Networking Computers Having Varying File Architectures;" U. S. Patent

16 Number 5,752,005, "Foreign File System Establishing Method which Uses a Native File

17 System Virtual Device Driver;" U. S. Patent Number 5,937,406, "File System Interface to a

18 Database;" U. S. Patent Number 5,864,853, "Portable File System Operable Under Various

19 Computer Environments;" and U. S. Patent Number 4,956,809, "Method for Canonical

20 Ordering of Binary Data for Portable Operating Systems." Foreign patents representative of

21 this approach include: Japan Patent Number 10247155A, "File System Interface for Data

22 Base;" Japan Patent Number 8137728A, "Portable File System and File Data Processing

23 Method;" Japan Patent Number 7230396A, "Mutual Constitution System for Different Kinds

24 of File System Forms;" and Japan Patent Number 10260877A, "Protocol Conversion System in

25 Client Server System, Method Therefor and Recording Medium Programmed and Recorded

26 with the Method." Publications of this approach include: "File Interface for Migrating

27 Applications to Enhanced Persistent Storage Platforms," IBM Technical Disclosure Bulletin,

28 June 1992, p. 182-183; "AS/400 OS/2 PC Support Shared Folders," id., Dec. 1989, p. 202-

29 205; "Method to Manage the Mapping of Logical to Physical Record," id., Dec. 1995, p. 261-

1   262; "Implicit Mapping of File Data," id., April 1995, p. 523-524; and "OS/2 Logical File

2   System," id., May. 1992, p. 370-371. Although this approach is a significant improvement

3   over merely converting the information format, it still suffers from the disadvantage of even

4   more permutations, where the permutations for each converter for a different pair of source and

5   target file systems ported to the different types of operating systems and computer hardware

6   architectures is also probably not commercially feasible.

7

8   Thus, there is a clearly felt need for a method, system and computer program product

9   for providing an improved extensible file access method for accessing a foreign file system

10   from a data processing system with a native file system, said foreign file system and said native

11   file system implementing different file system protocols.

SUMMARY OF THE INVENTION

The present invention comprises an extensible file access method for accessing a first foreign file system from a data processing system with a first native file system, said first foreign file system and said first native file system implementing different file system protocols.

In accordance with an aspect of a preferred embodiment of the present invention, an extensible file access method for accessing a foreign file system from a data processing system with a native file system, said foreign file system and said native file system implementing different file system protocols, comprises the steps of:

issuing a request according to the native file system protocol for data stored in the foreign file system;

translating the native file system request to an intermediate programming interface, wherein the intermediate programming interface is different from both the native file system protocol and the foreign file system protocol;

translating the intermediate file system request to the foreign file system protocol; and

returning to the data processing system a response from the foreign file system responsive to the translated request.

In accordance with another aspect of a preferred embodiment of the present invention, the extensible file access method is extended to support a second foreign file system by determining the second foreign file system protocol and by providing a translation from the intermediate programming interface to the second foreign file system protocol.

In accordance with another aspect of a preferred embodiment of the present invention, the extensible file access method is extended to support a second native file system by determining the native file system protocol and by providing a translation from the second native file system protocol to the intermediate programming interface.

1   In accordance with another aspect of a preferred embodiment of the present invention,

2   the intermediate programming interface comprises a set of generic access functions common to

3   the native file system protocol and the foreign file system protocol, and comprises a set of file

4   system specific functions which are not common to the file system protocols.

5

6   In accordance with another aspect of a preferred embodiment of the present invention,

7   the set of generic access functions common to the native file system protocol and the foreign

8   file system protocol are translated from the native file system protocol to the intermediate

9   programming interface which is then translated to the foreign file system protocol, and the set

10   of file system specific functions which are not common to the file system protocols are not

11   translated from the native file system protocol to the intermediate programming interface.

12

13   In accordance with another aspect of a preferred embodiment of the present invention,

14   the set of file system specific functions which are not common to the file system protocols

15   further comprises a set of extended native file system functions which have no equivalent

16   function in the foreign file system protocol.

17

18   In accordance with another aspect of a preferred embodiment of the present invention,

19   the set of extended native file system functions causes a predetermined response to be sent to

20   the data processing system.

21

22   In accordance with another aspect of a preferred embodiment of the present invention,

23   the set of file system specific functions which are not common to the file system protocols

24   further comprises and a set of extended foreign file system functions which have no equivalent

25   function in the native file system protocol.

26

27   In accordance with another aspect of a preferred embodiment of the present invention,

28   the set of extended foreign file system functions are passed through to the foreign file system in

29   an untranslated form.

1   A preferred embodiment of the present invention has the advantage of providing a

2   method for integrating existing applications which use a native file system with back-end data

3   management systems which use a separate foreign file system.

4

5   A preferred embodiment of the present invention has the advantage of allowing an

6   application written for the native file system to read and write data to a back-end application or

7   back-end data store without requiring file system modifications of that application.

8

9   A preferred embodiment of the present invention has the advantage of allowing the

10   native file system application to create, view and manipulate the meta-data for the back-end

11   application from the native file system application.

12

13   A preferred embodiment of the present invention has the advantage of allowing the

14   foreign file system application to appear as if it is written to the native file system.

15

16   A preferred embodiment of the present invention has the advantage of allowing the

17   native file system application to access the foreign file system as if it is a native file system.

18

19   A preferred embodiment of the present invention has the advantage of reducing the

20   complexity of supporting an additional native file system.

21

22   A preferred embodiment of the present invention has the advantage of reducing the

23   complexity of supporting an additional foreign file system.

24

25   A preferred embodiment of the present invention has the advantage of reducing the

26   complexity of translating from multiple native file system protocols to multiple foreign file

27   system protocols.

28

29   A preferred embodiment of the present invention has the advantage of allowing the

1 native file system application by use of the virtual file system to seamlessly access statically

2 stored files (such as File Transfer Protocol (FTP), Hypertext Transfer Protocol (HTTP),

3 hierarchical data base files, relational data base files, and object oriented database files) and

4 dynamically constructed files (such as Information Management System (IMS) transactions or

5 Customer Information Control System (CICS) transactions).

6

7 A preferred embodiment of the present invention has the advantage of providing a

8 consistent and potentially standard method for accessing back-end storage systems.

9

10 A preferred embodiment of the present invention has the advantage of providing a

11 unified storage access model which allows native file system applications and the native

12 operating system to seamlessly import and export data to back-end server systems via the

13 virtual file system by presenting the back-end systems in a way as to be indistinguishable from

14 the local file system.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention and the advantages thereof, reference is now made to the Description of the Preferred Embodiment in conjunction with the attached Drawings, in which:

Figure 1 is a block diagram of a distributed computer system which may be used in performing the method of an embodiment of the present invention, forming part of the apparatus of an embodiment of the present invention, and which may use the article of manufacture comprising a computer-readable storage medium having a computer program embodied in said medium which may cause the computer system to practice an embodiment of the present invention;

Figure 2 is a block diagram of an architecture of a preferred embodiment of the present invention; and

Figures 3 and 4 are flowcharts illustrating the operations preferred in carrying out a preferred embodiment of the present invention.

DESCRIPTION OF THE PREFERRED EMBODIMENT

1

2

3   Referring first to **Figure 1**, there is depicted a graphical representation of a data

4   processing system **8**, which may be utilized to implement the present invention. As may be

5   seen, data processing system **8** may include a plurality of networks, such as Local Area

6   Networks (LAN) **10** and **32**, each of which preferably includes a plurality of individual

7   computers **12** and **30**, respectively. Of course, those skilled in the art will appreciate that a

8   plurality of Intelligent Work Stations (IWS) coupled to a host processor may be utilized for

9   each such network. Each said network may also consist of a plurality of processors coupled via

10   a communications medium, such as shared memory, shared storage, or an interconnection

11   network. As is common in such data processing systems, each individual computer may be

12   coupled to a storage device **14** and/or a printer/output device **16** and may be provided with a

13   pointing device such as a mouse **17**.

14

15   The data processing system **8** may also include multiple mainframe computers, such as

16   mainframe computer **18**, which may be preferably coupled to LAN **10** by means of

17   communications link **22**. The mainframe computer **18** may also be coupled to a storage device

18   **20** which may serve as remote storage for LAN **10**. Similarly, LAN **10** may be coupled via

19   communications link **24** through a sub-system control unit/communications controller **26** and

20   communications link **34** to a gateway server **28**. The gateway server **28** is preferably an IWS

21   which serves to link LAN **32** to LAN **10**.

22

23   With respect to LAN **32** and LAN **10**, a plurality of documents or resource objects may

24   be stored within storage device **20** and controlled by mainframe computer **18**, as resource

25   manager or library service for the resource objects thus stored. Of course, those skilled in the

26   art will appreciate that mainframe computer **18** may be located a great geographic distance

27   from LAN **10** and similarly, LAN **10** may be located a substantial distance from LAN **32**. For

28   example, LAN **32** may be located in California while LAN **10** may be located within North

29   Carolina and mainframe computer **18** may be located in New York.

1	Software program code which employs the present invention is typically stored in the

2	memory of a storage device **14** of a stand alone workstation or LAN server from which a

3	developer may access the code for distribution purposes, the software program code may be

4	embodied on any of a variety of known media for use with a data processing system such as a

5	diskette or CD-ROM or may be distributed to users from a memory of one computer system

6	over a network of some type to other computer systems for use by users of such other systems.

7	Such techniques and methods for embodying software code on media and/or distributing

8	software code are well-known and will not be further discussed herein.

9

10	As will be appreciated upon reference to the foregoing, it is often desirable for a user

11	working on a workstation **12** to be able to access information or files stored on host storage

12	device **20** on the host 18. Such files are usually stored on host storage device **20** in accordance

13	with a host file system protocol which is different from the workstation file system protocol

14	used to store files on the workstation **12**. The present invention provides an extensible file

15	access method and virtual file system which allows an application executing on the workstation

16	**12**, having a native file system for files stored on the workstation **12**, to access files stored on

17	the host storage device **20**, the host storage files being stored in a foreign file system

18	implementing a different file system protocol from the workstation or native file system

19	protocol.

20

21	Referring next to **Figure 2**, there is shown a block diagram of an architecture of a

22	preferred embodiment of the present invention. The foreign file system **20** is accessed by

23	issuing a request according to the native file system protocol **285** for data stored in the foreign

24	file system **20**; translating the native file system request to an intermediate programming

25	interface **250**, wherein the intermediate programming interface **250** is different from both the

26	native file system protocol **285** and the foreign file system protocol (**255, 260,** or **265**);

27	translating the intermediate file system request to the foreign file system protocol; and

28	returning to the data processing system a response **295** from the foreign file system responsive

29	to the translated request. Multiple foreign file systems **235** and **240** may be supported by

1   determining a second foreign file system protocol and by providing a translation from the

2   intermediate programming interface to the second foreign file system protocol. Also, multiple

3   native file systems may be supported by determining a second native file system protocol and

4   by providing a translation from the second native file system protocol to the intermediate

5   programming interface.

6

7   The intermediate programming interface comprises a set of generic access functions

8   common to the native file system protocol and the foreign file system protocol and a set of file

9   system specific functions which are not common to the file system protocols. The set of

10   generic access functions common to the native file system protocol and the foreign file system

11   protocol are translated from the native file system protocol to the intermediate programming

12   interface which is then translated to the foreign file system protocol, and the set of file system

13   specific functions which are not common to the file system protocols are not translated from

14   the native file system protocol to the intermediate programming interface which is then

15   translated to the foreign file system protocol. Existing applications which use a native file

16   system may be more easily integrated with back-end data management systems which use a

17   separate foreign file system without requiring file system modifications of the existing

18   application. A foreign file system application may appear as if it is written to the native file

19   system, and a native file system application may access the foreign file system as if it is a

20   native file system. A dynamic virtual file system may be constructed to support a consistent

21   standard interface to seamlessly access statically stored files and dynamically constructed files.

22

23   Sash **200** is a replacement for a conventional Common Internet File System (CIFS)

24   server. It consists of a Server Message Block (SMB) server **210** which interfaces to a client

25   **215**, and one or more FSModule backends **220, 225**, and **230** which interface on one side to

26   the SMB server **210** and on the other side to the backends **235, 240**, and **245**. The SMB server

27   **210** includes the server itself, the logging system and the control file that manages the SMB

28   server. The design and implementation of the SMB server is based on an Internet-Draft, A

29   Common Internet File System (CIFS) Protocol,

1   http://msdn.microsoft.com/workshop/networking/cifs/default.asp.

2

3

4   The backend, FFSModule **220**, exposes ISash **250** which is a Common Object Model

5   (COM) interface to communicate with the SMB server. The FFSModule receives requests

6   from the SMB server through ISash, translates them to appropriate application programming

7   interfaces (APIs) **255**, **260**, and **265** provided by client-API dynamic link libraries (dlls). The

8   FFSModule then returns the pertinent information to the SMB server.

9

10   A COM interface, ISash **250**, defines the intermediate programming interface between

11   the SMB **210** and the FFSModule **220**, **225**, and **230** .   The ISash interface comprises disk

12   type calls and is described in **Table A**.

13

14   FFSModule is a COM object. When the network command "net use devicename:

15   \\SMBservername\sharename" **270** is issued, the SMB **210** creates a new instance of

16   FFSModule object **220** associated with the given sharename **275** and acquires the ISash

17   interface pointer. The "SMBservername" **280** is the name of the SMB server, and "sharename"

18   **275** is a system name or a dataset name provided by a user. After SMB gets the ISash pointer,

19   it sends the first request to FFSModule to mount the sharename to a drive letter. Once a system

20   **235** or a data set is mounted, it is simply treated as if it was a local native file system drive.

	1	The following **Table A** is the list of requests that can come into SMB (a native file
	2	system protocol), the translated request (intermediate programming interface) to FFSModule
	3	from SMB, and the translated API calls made by FFSModule (foreign file system protocol) to
	4	obtain the necessary data from the file system, an MVS file system in this example:

5   _____
6
7
8   Referring now to **Figure 3** and **Figure 4**, the flowcharts illustrate the operations

9   preferred in carrying out the preferred embodiment of the present invention. In the flowcharts,

10   the graphical conventions of a diamond for a test or decision and a rectangle for a process or

11   function are used. These conventions are well understood by those skilled in the art, and the

12   flowcharts are sufficient to enable one of ordinary skill to write code in any suitable computer

13   programming language for an assembler, interpreter, or compiler.

14

15   Referring first to **Figure 3**, after the start **310** of the process **300**, a native request from a

16   client on the workstation to the remote data processing system to open a foreign file in the

17   foreign file is generated in process block **320**. Responsive to the request, process block **330**

18   determines the native file system protocol; and process block **340** determines the foreign file

19   system protocol. Thereafter, process block **350** translates the native file system request to an

20   intermediate programming interface, wherein the intermediate programming interface is

21   different from both the native file system protocol and the foreign file system protocol. Process

22   block **360** then translates the intermediate file system request to the foreign file system

23   protocol. Thereafter, process block **370** issues the translated request to the foreign file system;

24   and process block **380** returns to the client a response from the foreign file system responsive to

25   the translated request. The process then ends at process block **390**.

26

27   Referring now to **Figure 4**, process **400** is an expansion of the translation process steps

28   **340**, **350**, **360**, and **370** of **Figure 3**. Decision block **410** determines if the native file system

29   request is a common access function, an access function common to both the native file system

30   protocol and the foreign file system protocol. If the native file system request is a common

1   access function, then process block **420** translates the common access function from the native

2   file system protocol to the intermediate programming interface and then translates it from the

3   intermediate system protocol to the foreign file system protocol. Thereafter, processing

4   continues to process block **380** which returns the response to the client.

5

6   Returning now to decision block **410**, if the native file system request is not a common

7   access function, then decision block **440** determines if the native file system request is an

8   extended native function, a native file system functions which have no equivalent function in

9   the foreign file system protocol. If the native file system request is an extended native function,

10   then process block **450** prepare a predetermined response to be sent to the client, preferably

11   indicating the inability of the foreign file system to service the request. Thereafter, processing

12   continues to process block **380** which returns the response to the client.

13

14   Returning now to decision block **440**, if the native file system request is not an

15   extended native function, then decision block **460** determines if the native file system request is

16   an extended foreign function, a foreign file system function which has no equivalent function

17   in the native file system protocol. If the native file system request is an extended foreign

18   function, then process block **470** passes through the extended foreign function to the foreign

19   file system in an untranslated form. Thereafter, processing continues to process block **380**

20   which returns the response from the extended foreign function to the client.

21

22   Returning now to decision block **460**, if the native file system request is not an

23   extended foreign function, then process block **480** returns an error to the client as the request

24   was neither a common, extended native, nor extended foreign function.

25

26   Using the foregoing specification, the invention may be implemented using standard

27   programming and/or engineering techniques using computer programming software, firmware,

28   hardware or any combination or sub-combination thereof. Any such resulting program(s),

29   having computer readable program code means, may be embodied within one or more

1   computer usable media such as fixed (hard) drives, disk, diskettes, optical disks, magnetic tape,

2   semiconductor memories such as Read-Only Memory (ROM), Programmable Read-Only

3   Memory (PROM), etc., or any memory or transmitting device, thereby making a computer

4   program product, i.e., an article of manufacture, according to the invention. The article of

5   manufacture containing the computer programming code may be made and/or used by

6   executing the code directly or indirectly from one medium, by copying the code from one

7   medium to another medium, or by transmitting the code over a network.   An apparatus for

8   making, using, or selling the invention may be one or more processing systems including, but

9   not limited to, central processing unit (CPU), memory, storage devices, communication links,

10 communication devices, servers, input/output (I/O) devices, or any sub-components or

11 individual parts of one or more processing systems, including software, firmware, hardware or

12 any combination or sub-combination thereof, which embody the invention as set forth in the

13 claims.

14

15 User input may be received from the keyboard, mouse, pen, voice, touch screen, or any

16 other means by which a human can input data to a computer, including through other programs

17 such as application programs.

18

19 One skilled in the art of computer science will easily be able to combine the software

20 created as described with appropriate general purpose or special purpose computer hardware to

21 create a computer system and/or computer sub-components embodying the invention and to

22 create a computer system and/or computer sub-components for carrying out the method of the

23 invention. Although the present invention has been particularly shown and described with

24 reference to a preferred embodiment, it should be apparent that modifications and adaptations

25 to that embodiment may occur to one skilled in the art without departing from the spirit or

26 scope of the present invention as set forth in the following claims.
